Regression *p*-values

Recall the regression model

$$Y_i \stackrel{ind}{\sim} N(\mu_i, \sigma^2), \qquad \mu_i = \beta_0 + \beta_1 X_{i,1} + \dots + \beta_p X_{i,p}$$

A common hypothesis test is

$$H_0: \beta_j = 0$$
 versus $H_A: \beta_j \neq 0$

which has

$$p$$
-value = $2P(T > |t|)$

where $T \sim t_{n-(p+1)}$ and $t = \hat{\beta}_j / SE(\beta_j)$.

Example Regression Output

```
Call:

Bayesian Posterior Probabilities

With prior $p(\beta, \sigma^2) \propto 1/\sigma^2$, we have

$$\beta_j | y \sim t_{n-(p+1)} \left(\hat{\beta}_j, SE(\beta_j)^2 \right).$$

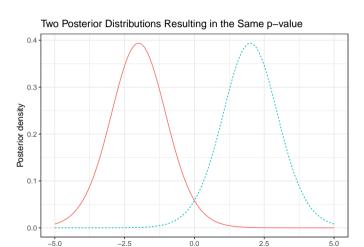

Thus

$$P(\beta_j > 0 | y) = P\left(\frac{\beta_j - \hat{\beta}_j}{SE(\beta_j)} > \frac{0 - \hat{\beta}_j}{SE(\beta_j)} \middle| y\right) = P(T > -t)$$

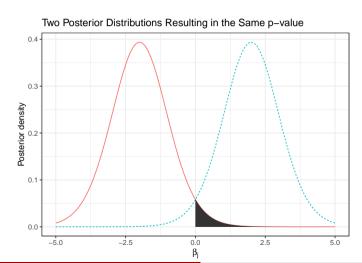

which is very close to

$$p$$
-value = $2P(T > |t|)$.

Interpreting Regression *p*-values as Posterior Probabilities

Suppose we have a *p*-value for $H_0: \beta_j = 0$ vs $H_A: \beta_j \neq 0$. Then

• If $\hat{\beta}_j < 0$, then

$$P(\beta_j > 0|y) = p$$
-value/2.

• If $\hat{\beta}_j > 0$, then

$$P(\beta_j < 0|y) = p$$
-value/2.

Alternatively,

• If $\hat{\beta}_i < 0$, then

$$P(\beta_j < 0|y) = 1 - p$$
-value/2.

• If $\hat{\beta}_i > 0$, then

$$P(\beta_i > 0|y) = 1 - p$$
-value/2.

Example Interpretation

		Estimate Std	. Error t	value	Pr(> t)
(I:	ntercept)	33.23	0.35	96.09	0.00
Co	nditionsSlow	-2.05	0.72	-2.82	0.01
10	g(NetToWinner)	0.28	0.03	9.46	0.00
Co	nditionsSlow:log(NetToWinner)	0.09	0.07	1.32	0.19

Intercept	$P(\beta_0 > 0 y) \approx 1$
ConditionsSlow	$P(\beta_1 < 0 y) \approx 0.99$
log(NetToWinner)	$P(\beta_2 > 0 y) \approx 1$
ConditionsSlow:log(NetToWinner)	$P(\beta_3 > 0 y) \approx 0.90$

Summary

Suppose we have a regression p-value for $H_0: \beta_j = 0$ vs $H_A: \beta_j \neq 0$. Then

• If $\hat{\beta}_j < 0$, then

$$P(\beta_j < 0|y) = 1 - p$$
-value/2.

• If $\hat{\beta}_j > 0$, then

$$P(\beta_j > 0|y) = 1 - p\text{-value}/2.$$
